Virtual Processor Station

Paratech Solutions adopt an open systems approach with the introduction of a new parallel processing workstation.

Based on industry standard parallel processing hardware, the 'VPS' series of development platforms use the TAOS operating system to give an homogeneous, scalable, multi-processor, multi-user computer architecture.

TAOS provides an integrated development environment for parallel processing, isolating the developer from network details, providing automatic balancing of network loads and communications. The ANSI C compiler for TAOS, provides full support for network management and the development and debugging of parallel systems.

The Open Systems strategy of the 'VPS' extends to all existing transputer development software. This includes INMOS toolsets, 3L compilers, Perihelion's Helios, Real Time Kernel, Windows File Servers, Express and others.

Special features of TAOS include the transparent integration of transputers with the 50Mflop TMS320C40 on Paratech's PST208, and a high performance multi-window GUI.

A minimum system configuration for the 'VPS' comprises an 8 Mflops engine, with TAOS and ANSI C compiler, PC host with 40MByte hard disk, and VGA graphics.

There are no limitations on system expansion. The number of processors can be increased at any time, by adding further compute modules and extra users may be introduced to the network by including additional PC based servers.
